

# Agent architectures and hierarchical control

## Overview:

- Agents and Robots
- Agent systems and architectures
- Agent controllers
- Hierarchical controllers

# Example: smart house

- A smart house will monitor your use of essentials, and buy them before you run out.

Example: snack buying agent that ensures you have a supply of chips:

- ▶ **abilities:** buy chips (and have them delivered)
- ▶ **goals:**
- ▶ **stimuli:**
- ▶ **prior knowledge:**

# Agent Systems

A **agent system** is made up of a **agent** and an **environment**.

- An agent receives **stimuli** from the environment
- An agent carries out **actions** in the environment.

# Agent System Architecture

An **agent** is made up of a **body** and a **controller**.

- An agent interacts with the environment through its body.
- The **body** is made up of:
  - ▶ **sensors** that interpret stimuli
  - ▶ **actuators** that carry out actions
- The controller receives **percepts** from the body.
- The controller sends **commands** to the body.
- The body can also have reactions that are not controlled.

# Implementing a controller

- A **controller** is the **brains** of the agent.
- Agents are situated in time, they receive sensory data in time, and do actions in time.
- Controllers have (limited) memory and (limited) computational capabilities.
- The controller specifies the command at every time.
- The command at any time can depend on the current and previous percepts.

# The Agent Functions

- Let  $T$  be the set of time points.
- A **percept trace** is a sequence of all past, present, and future percepts received by the controller.
- A **command trace** is a sequence of all past, present, and future commands output by the controller.

# The Agent Functions

- Let  $T$  be the set of time points.
- A **percept trace** is a sequence of all past, present, and future percepts received by the controller.
- A **command trace** is a sequence of all past, present, and future commands output by the controller.
- A **transduction** is a function from percept traces into command traces.

# The Agent Functions

- Let  $T$  be the set of time points.
- A **percept trace** is a sequence of all past, present, and future percepts received by the controller.
- A **command trace** is a sequence of all past, present, and future commands output by the controller.
- A **transduction** is a function from percept traces into command traces.
- A transduction is **causal** if the command trace up to time  $t$  depends only on percepts up to  $t$ .

# The Agent Functions

- Let  $T$  be the set of time points.
- A **percept trace** is a sequence of all past, present, and future percepts received by the controller.
- A **command trace** is a sequence of all past, present, and future commands output by the controller.
- A **transduction** is a function from percept traces into command traces.
- A transduction is **causal** if the command trace up to time  $t$  depends only on percepts up to  $t$ .
- A **controller** is an implementation of a causal transduction.
- An agent's **history** at time  $t$  is sequence of past and present percepts and past commands.
- A causal transduction specifies a function from an agent's history at time  $t$  into its action at time  $t$ .

# Belief States

- An agent doesn't have access to its entire history. It only has access to what it has remembered.

# Belief States

- An agent doesn't have access to its entire history. It only has access to what it has remembered.
- The **memory** or **belief state** of an agent at time  $t$  encodes all of the agent's history that it has access to.
- The belief state of an agent encapsulates the information about its past that it can use for current and future actions.

# Belief States

- An agent doesn't have access to its entire history. It only has access to what it has remembered.
- The **memory** or **belief state** of an agent at time  $t$  encodes all of the agent's history that it has access to.
- The belief state of an agent encapsulates the information about its past that it can use for current and future actions.
- At every time a controller has to decide on:
  - ▶ What should it do?
  - ▶ What should it remember?  
(How should it update its memory?)— as a function of its percepts and its memory.

# Controller

# Functions implemented in a controller

For discrete time, a controller implements:

- **belief state function**  $remember(belief\_state, percept)$ , returns the next belief state.
- **command function**  $command(memory, percept)$  returns the command for the agent.

# Example: smart house

- A smart house will monitor your use of essentials, and buy them before you run out.

Example: snack buying agent:

- ▶ **abilities:** buy chips (and have them delivered)
  - ▶ **goals:**
  - ▶ **stimuli:**
  - ▶ **prior knowledge:**
- Percept trace:
- Control trace:
- Transduction:
- Belief state:
- Belief state transition function:
- Control Function:

# Implemented Example

- Percepts: price, number in stock
- Action: number to buy
- Belief state: average
- controller:
  - ▶ if  $price < 0.9 * average$  and  $instock < 60$  buy 48
  - ▶ else if  $instock < 12$  buy 12
  - ▶ else buy 0

# Implemented Example

- Percepts: price, number in stock
- Action: number to buy
- Belief state: average
- controller:
  - ▶ if  $price < 0.9 * average$  and  $instock < 60$  buy 48
  - ▶ else if  $instock < 12$  buy 12
  - ▶ else buy 0
- Belief state transition function:

$$average := average + (price - average) * 0.05$$

# Implemented Example

- Percepts: price, number in stock
- Action: number to buy
- Belief state: average
- controller:
  - ▶ if  $price < 0.9 * average$  and  $instock < 60$  buy 48
  - ▶ else if  $instock < 12$  buy 12
  - ▶ else buy 0
- Belief state transition function:

$$average := average + (price - average) * 0.05$$

This maintains a rolling average that (eventually) weights more recent prices more.

(Implemented in AIPython distribution; <http://aipython.org>)
